

ABSTRACT

A showering device for the intimate region is provided for colon irrigation. The device comprises a housing in the form of a hand-grip body, a shut-off valve, a housing closure, and a head portion. An insertion rinsing tube may be exchangeably and sealably connected to the housing through the housing closure. An existing shower head hose, for example, is used to supply water via the shut-off cock located on the housing body. The shut off cock is opened for the inner and outer washing process only when the insertion rinsing tube is readily held, while an individual is sitting on the water closet or bidet, under the body in an upright manner.
